http://www.scipy.org/Documentation

Topics

- Introduction to Python
- Numeric Computing
- SciPy and its libraries

What Is Python?

ONE LINER

Python is an interpreted programming language that allows you to do almost anything possible with a compiled language (C/C++/Fortran) without requiring all the complexity.

PYTHON HIGHLIGHTS

- **Automatic garbage collection**
- **Dynamic typing**
- **Interpreted and interactive**
- **Object-oriented**
- **"Batteries Included"**
- **Free**
- **Portable**
- **Easy to Learn and Use**
- **Truly Modular**

Who is using Python?

NATIONAL SPACE TELESCOPE LABORATORY

Data processing and calibration for instruments on the Hubble Space Telescope.

INDUSTRIAL LIGHT AND MAGIC

Digital Animation

PAINT SHOP PRO 8

Scripting Engine for JASC PaintShop Pro 8 photo-editing

CONOCOPHILLIPS

Oil exploration tool suite

LAWRENCE LIVERMORE NATIONAL LABORATORIES

Scripting and extending parallel physics codes. pyMPI is their doing.

WALT DISNEY

Digital animation development environment.

REDHAT

Anaconda, the Redhat Linux installer program, is written in Python.

ENTHOUGHT

Geophysics and Electromagnetics engine scripting, algorithm development, and visualization

Language Introduction

Interactive Calculator

```
# adding two values
>>> 1 + 1
2
# setting a variable
>>> a = 1
>>> a
1
# checking a variables type
>>> type(a)
<type 'int'>
# an arbitrarily long integer
>>> a = 1203405503201
>>> a
1203405503201L
>>> type(a)
<type 'long'>
>>>> type(a).__name__=='long'
True
>>>> print type.__doc__
type(name, bases, dict)
```

```
# real numbers
>>> b = 1.2 + 3.1
>>> b
4.2999999999999998
>>> type(b)
<type 'float'>
# complex numbers
>>> c = 2+1.5j
>>> c
(2+1.5j)
```

The four numeric types in Python on 32-bit architectures are:
- **integer** (4 byte)
- **long integer** (any precision)
- **float** (8 byte like C's double)
- **complex** (16 byte)

The Numeric module, which we will see later, supports a larger number of numeric types.

Complex Numbers

CREATING COMPLEX NUMBERS

```
# Use "j" or "J" for imaginary
# part. Create by "(real+imagj)",
# or "complex(real, imag)" .
>>> 1j * 1J
(-1+0j)
>>> 1j * complex(0,1)
 (-1+0j)
>>> (1+2j)/(1+1j)
(1.5+0.5j)
```

EXTRACTING COMPONENTS

```
# to extract real and im
# component
>>> a=1.5+0.5j
>>> a.real
1.5
>>> a.imag
0.5
```

ABSOLUTE VALUE

```
>>> a=1.5+0.5j
>>> abs(a)
1.5811388
```

Strings

CREATING STRINGS

```
# using double quotes
>>> s = "hello world"
>>> print s
hello world
# single quotes also work
>>> s = 'hello world'
>>> print s
hello world
```

STRING OPERATIONS

```
# concatenating two strings
>>> "hello " + "world"
'hello world'

# repeating a string
>>> "hello " * 3
'hello hello hello '
```

STRING LENGTH

```
>>> s = "12345"
>>> len(s)
5
```

FORMAT STRINGS

```
# the % operator allows you
# to supply values to a
# format string.  The format
# string follows
# C conventions.
>>> s = "some numbers:"
>>> x = 1.34
>>> y = 2
>>> s = "%s %f, %d" % (s,x,y)
>>> print s
some numbers: 1.34, 2
```

The strings

```
>>> s = "hello world"
>>> s.split()
['hello', 'world']

>>> ' '.join(s.split())
hello world

>>> s.replace('world' ,'Mars')
'hello Mars'

# strip whitespace
>>> s = "\t   hello   \n"
>>> s.strip()
'hello'
```

```
Regular expressions:
re.match(regex,subject)
re.search(regexp,subject)
re.group()
re.groups()
re.sub(regex, replacement,sub)

>>import re
>>s="The time is 12:30pm!"
>>m=re.match(".*time is (.*)pm", s))
>>m.group(1)
'12:30'
>>m.groups()
('12:30',)
>>m=re.search(r'time.*(\d+:\d+)pm',s)
>>m.group(1)
'12:30'
>>re.sub(r'\d+:\d+','2:10',s)
'The time is 2:10pm!'
```

Multi-line Strings

```
# triple quotes are used
# for mutli-line strings
>>> a = """hello
... world"""
>>> print a
hello
world

# multi-line strings using
# "\" to indicate
continuation
>>> a = "hello " \
...     "world"
>>> print a
hello world
```

```
# including the new line
>>> a = "hello\n" \
...     "world"
>>> print a
hello
world
```

List objects

LIST CREATION WITH BRACKETS

```
>>> l = [10,11,12,13,14]
>>> print l
[10, 11, 12, 13, 14]
```

CONCATENATING LIST

```
# simply use the + operator
>>> [10, 11] + [12,13]
[10, 11, 12, 13]
```

REPEATING ELEMENTS IN LISTS

```
# the multiply operator
# does the trick.
>>> [10, 11] * 3
[10, 11, 10, 11, 10, 11]
```

range(start, stop, step)

```
# the range method is helpful
# for creating a sequence
>>> range(5)
[0, 1, 2, 3, 4]

>>> range(2,7)
[2, 3, 4, 5, 6]

>>> range(2,7,2)
[2, 4, 6]
```

Indexing

RETREIVING AN ELEMENT

```
# list
# indices: 0  1  2  3  4
  >>>  l = [10,11,12,13,14]
  >>>  l[0]
  10
```

SETTING AN ELEMENT

```
>>> l[1] = 21
>>> print l
[10, 21, 12, 13, 14]
```

OUT OF BOUNDS

```
>>> l[10]
Traceback (innermost last):
File "<interactive input>",line 1,in ?
IndexError: list index out of range
```

NEGATIVE INDICES

```
# negative indices count
# backward from the end of
# the list.
#
# indices: -5 -4 -3 -2 -1
  >>>   l = [10,11,12,13,14]

  >>> l[-1]
  14
  >>> l[-2]
  13
```

The first element in an array has index=0 as in C. *Take note Fortran programmers!*

More on list objects

LIST CONTAINING MULTIPLE TYPES

```
# list containing integer,
# string, and another list.
>>> l = [10,'eleven',[12,13]]
>>> l[1]
'eleven'
>>> l[2]
[12, 13]

# use multiple indices to
# retrieve elements from
# nested lists.
>>> l[2][0]
12
```

LENGTH OF A LIST

```
>>> len(l)
3
```

DELETING OBJECT FROM LIST

```
# use the del keyword
>>> del l[2]
>>> l
[10,'eleven']
```

DOES THE LIST CONTAIN x ?

```
# use in or not in
>>> l = [10,11,12,13,14]
>>> 13 in l
1
>>> 13 not in l
0
```

A few methods for list objects

some_list.append(x)

Add the element x to the end
of the list, `some_list`.

some_list.count(x)

Count the number of times x occurs in the list.

some_list.index(x)

Return the index of the first occurrence of x in the list.

some_list.remove(x)

Delete the first occurrence of x from the list.

some_list.reverse( )

Reverse the order of elements in the list.

some_list.sort(cmp)

By default, sort the elements in ascending order. If a compare function is given, use it to sort the list.

Slicing

`var[lower:upper]`

Slices extract a portion of a sequence by specifying a lower and upper bound. The extracted elements start at lower and go up to, *but do not include*, the upper element. Mathematically the range is [lower,upper).

SLICING LISTS

```
# indices: 0  1  2  3  4
   >>> l = [10,11,12,13,14]
   # [10,11,12,13,14]
   >>> l[1:3]
   [11, 12]

# negative indices work also
>>> l[1:-2]
[11, 12]
>>> l[-4:3]
[11, 12]
```

OMITTING INDICES

```
# omitted boundaries are
# assumed to be the beginning
# (or end) of the list.

# grab first three elements
>>> l[:3]
[10,11,12]
# grab last two elements
>>> l[-2:]
[13,14]
```

List methods in action

```
>>> l = [10,21,23,11,24]

# add an element to the list
>>> l.append(11)
>>> print l
[10,21,23,11,24,11]

# how many 11s are there?
>>> l.count(11)
2

# where does 11 first occur?
>>> l.index(11)
3
```

```
# remove the first 11
>>> l.remove(11)
>>> print l
[10,21,23,24,11]

# sort the list
>>> l.sort()
>>> print l
[10,11,21,23,24]

# reverse the list
>>> l.reverse()
>>> print l
[24,23,21,11,10]
```

Mutable vs. Immutable

MUTABLE OBJECTS

```
# Mutable objects, such as
# lists, can be changed
# in-place.

# insert new values into list
>>> l = [10,11,12,13,14]
>>> l[1:3] = [5,6]
>>> print l
[10, 5, 6, 13, 14]
```

The cStringIO module treats strings like a file buffer and allows insertions. It's useful when working with large strings or when speed is paramount.

IMMUTABLE OBJECTS

```
# Immutable objects, such as
# strings, cannot be changed
# in-place.

# try inserting values into
# a string
>>> s = 'abcde'
>>> s[1:3] = 'xy'
Traceback (innermost last):
File "<interactive input>",line 1,in ?
TypeError: object doesn't support
           slice assignment

# here's how to do it
>>> s = s[:1] + 'xy' + s[3:]
>>> print s
'axyde'
```

Dictionaries

Dictionaries store *key/value* pairs. Indexing a dictionary by a *key* returns the *value* associated with it.

DICTIONARY EXAMPLE

```
# create an empty dictionary using curly brackets
>>> record = {}
>>> record['first'] = 'Jmes'
>>> record['last'] = 'Maxwell'
>>> record['born'] = 1831
>>> print record
{'first': 'Jmes', 'born': 1831, 'last': 'Maxwell'}
# create another dictionary with initial entries
>>> new_record = {'first': 'James', 'middle':'Clerk'}
# now update the first dictionary with values from the new one
>>> record.update(new_record)
>>> print record
{'first': 'James', 'middle': 'Clerk', 'last':'Maxwell', 'born':
1831}
```

A few dictionary methods

some_dict.clear( )

Remove all key/value pairs from the dictionary, `some_dict`.

some_dict.copy( )

Create a copy of the dictionary

some_dict.has_key(x)

Test whether the dictionary contains the key `x`.

some_dict.keys( )

Return a list of all the keys in the dictionary.

some_dict.values( )

Return a list of all the values in the dictionary.

some_dict.items( )

Return a list of all the key/value pairs in the dictionary.

Dictionary methods in action

```
>>> d = {'cows': 1,'dogs':5,
...       'cats': 3}

# create a copy.
>>> dd = d.copy()
>>> print dd
{'dogs':5,'cats':3,'cows': 1}

# test for chickens.
>>> d.has_key('chickens')
0

# get a list of all keys
>>> d.keys()
['cats','dogs','cows']
```

```
# get a list of all values
>>> d.values()
[3, 5, 1]

# return the key/value pairs
>>> d.items()
[('cats', 3), ('dogs', 5),
 ('cows', 1)]

# clear the dictionary
>>> d.clear()
>>> print d
{}
```

Tuples

Tuples are a sequence of objects just like lists. Unlike lists, tuples are immutable objects. While there are some functions and statements that require tuples, they are rare. A good rule of thumb is to use lists whenever you need a generic sequence.

TUPLE EXAMPLE

```
# tuples are built from a comma separated list enclosed by ( )
>>> t = (1,'two')
>>> print t
(1,'two')
>>> t[0]
1
# assignments to tuples fail
>>> t[0] = 2
Traceback (innermost last):
File "<interactive input>", line 1, in ?
TypeError: object doesn't support item assignment
```

Multiple assignments

```
# creating a tuple without ()
>>> d = 1,2,3
>>> d
(1, 2, 3)
```

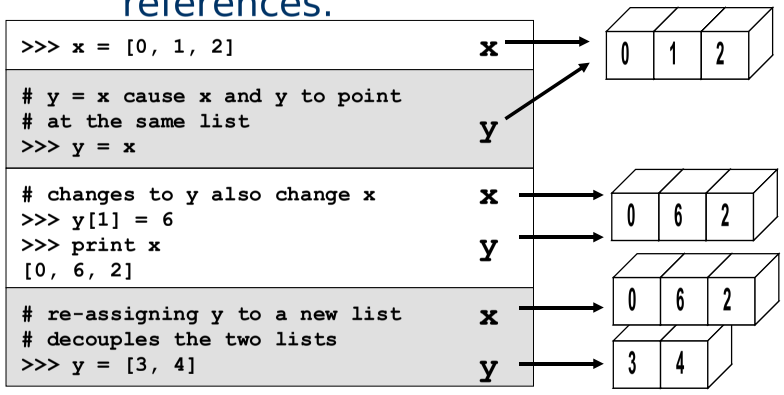
```
# multiple assignments from a
# tuple
>>> a,b,c = d
>>> print b
2
```

```
# multiple assignments
>>> a,b,c = 1,2,3
>>> print b
2
```

```
# also works for lists
>>> a,b,c = [1,2,3]
>>> print b
2
```

Assignment

Assignment creates object references.



If statements

`if/elif/else` provide conditional execution of code blocks.

IF STATEMENT FORMAT

```
if <condition>:
      <statements>
elif <condition>:
      <statements>
else:
      <statements>
```

IF EXAMPLE

```
# a simple if statement
>>> x = 10
>>> if x > 0:
...       print 1
... elif x == 0:
...       print 0
... else:
...       print -1
... < hit return >
1
```

Test Values

- True means any non-zero number or non-empty object
- False means not true: zero, empty object, or **None**

EMPTY OBJECTS

```
# empty objects evaluate false
>>> x = []
>>> if x:
...     print 1
... else:
...     print 0
... < hit return >
0
```

For loops

For loops iterate over a sequence of objects.

```
for <loop_var> in <sequence>:
    <statements>
```

TYPICAL SCENARIO

```
>>> for i in range(5):
...     print i,
... < hit return >
0 1 2 3 4
```

LOOPING OVER A STRING

```
>>> for i in 'abcde':
...     print i,
... < hit return >
a b c d e
```

LOOPING OVER A LIST

```
>>> l=['dogs','cats','bears']
>>> accum = ''
>>> for item in l:
...     accum = accum + item
...     accum = accum + ' '
... < hit return >
>>> print accum
dogs cats bears
```

While loops

While loops iterate until a condition is met.

```
while <condition>:
    <statements>
```

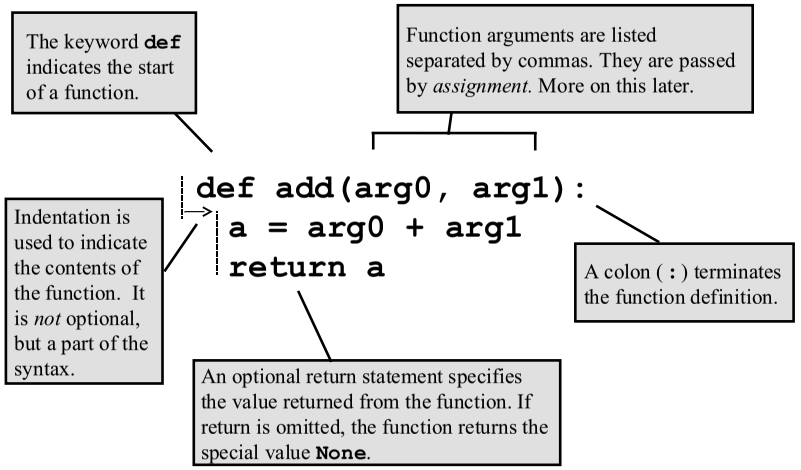
WHILE LOOP

```
# the condition tested is
# whether lst is empty.
>>> lst = range(3)
>>> while lst:
...     print lst
...     lst = lst[1:]
... < hit return >
[0, 1, 2]
[1, 2]
[2]
```

BREAKING OUT OF A LOOP

```
# breaking from an infinite
# loop.
>>> i = 0
>>> while 1:
...     if i < 3:
...         print i,
...     else:
...         break
...     i = i + 1
... < hit return >
0 1 2
```

Anatomy of a function



Our new function in action

```
# We'll create our function
# on the fly in the
# interpreter.
>>> def add(x,y):
...     a = x + y
...     return a

# test it out with numbers
>>> x = 2
>>> y = 3
>>> add(x,y)
5
```

```
# how about strings?
>>> x = 'foo'
>>> y = 'bar'
>>> add(x,y)
'foobar'

# functions can be assigned
# to variables
>>> func = add
>>> func(x,y)
'foobar'
```

```
# how about numbers and strings?
>>> add('abc',1)
Traceback (innermost last):
File "<interactive input>", line 1, in ?
File "<interactive input>", line 2, in add
TypeError: cannot add type "int" to string
```

More about functions

```
# Every function returns
# a value (or NONE)
# but you don't need to
# specify returned type!

# Function documentation
>>> def add(x,y):
...     """this function
...     adds two numbers"""
...     a = x + y
...     return a

# You can always retrieve
# function documentation
>>> print add.__doc__

this function
adds two numbers
```

```
# FUNCTIONAL PROGRAMMING:
# "map(function, sequence)"
>>> def cube(x): return
x*x*x ...
>>> map(cube, range(1, 6))
[1, 8, 27, 64, 125]

# "reduce (function,
sequence)"
>>> def add(x,y): return x+y
...
>>> reduce(add, range(1, 11))
55
# "filter (function,
sequence)"
>>> def f(x): return x % 2 !=
0
...
>>> filter(f, range(2, 10))
[3, 5, 7, 9]
```

Even more on functions

```
# buld-in function "dir" is
# used to list all
# definitions in a module
>>> import scipy
>>> dir(scipy)
.......................
...<a lot of stuf>...
.......................
```

```
# Lambda function:
# Python supports one-line mini-
# functions on the fly.
# Borrowed from Lisp, lambda
# functions can be used anywhere
# a function is required.
>>> def f(x): return x*x
>>> map(f, range(5))
[0, 1, 4, 9, 16]
>> map(lambda x: x*x, range(5))
[0, 1, 4, 9, 16]
```

```
# more on lambda function:
>>> a=range(10)
>>> a.sort(lambda x,y: cmp(y,x))
>>> print a
 [9, 8, 7, 6, 5, 4, 3, 2, 1, 0]
>>> map(lambda x: x*2+10, range(5))
 [10, 12, 14, 16, 18]
>>> print reduce(lambda x,y: x+y, range(5))
 10
```

Modules

EX1.PY

```
# ex1.py

PI = 3.1416

def sum(lst):
    tot = lst[0]
    for value in lst[1:]:
        tot = tot + value
    return tot

l = [0,1,2,3]
print sum(l), PI
```

FROM SHELL

```
[ej@bull ej]$ python ex1.py
6, 3.1416
```

FROM INTERPRETER

```
# load and execute the module
>>> import ex1
6, 3.1416
# get/set a module variable.
>>> ex1.PI
3.1415999999999999
>>> ex1.PI = 3.14159
>>> ex1.PI
3.1415899999999999
# call a module variable.
>>> t = [2,3,4]
>>> ex1.sum(t)
9
```

Modules *cont.*

INTERPRETER

```
# load and execute the module
>>> import ex1
6, 3.1416
< edit file >
# import module again
>>> import ex1
# nothing happens!!!

# use reload to force a
# previously imported library
# to be reloaded.
>>> reload(ex1)
10, 3.14159
```

EDITED EX1.PY

```
# ex1.py version 2

PI = 3.14159

def sum(lst):
    tot = 0
    for value in lst:
        tot = tot + value
    return tot

l = [0,1,2,3,4]
print sum(l), PI
```

Modules *cont. 2*

Modules can be executable scripts or libraries or both.

EX2.PY

```
" An example module "

PI = 3.1416

def sum(lst):
    """ Sum the values in a
        list.
    """
    tot = 0
    for value in lst:
        tot = tot + value
    return tot
```

EX2.PY CONTINUED

```
def add(x,y):
    " Add two values."
    a = x + y
    return a

def test():
    l = [0,1,2,3]
    assert( sum(l) == 6)
    print 'test passed'

# this code runs only if this
# module is the main program
if __name__ == '__main__':
    test()
```

Classes

SIMPLE PARTICLE CLASS

```
>>> class particle:
...     # Constructor method
...     def __init__(self,mass, velocity):
...             # assign attribute values of new object
...             self.mass = mass
...             self.velocity = velocity
...     # method for calculating object momentum
...     def momentum(self):
...             return self.mass * self.velocity
...     # a "magic" method defines object's string representation
...     def __repr__(self):
...             msg = "(m:%2.1f, v:%2.1f)" % (self.mass,self.velocity)
...             return msg
```

EXAMPLE

```
>>> a = particle(3.2,4.1)
>>> a
(m:3.2, v:4.1)
>>> a.momentum()
13.119999999999999
```

Reading files

FILE INPUT EXAMPLE

```
>>> results = []
>>> f = open('c:\\rcs.txt','r')

# read lines and discard header
>>> lines = f.readlines()[1:]
>>> f.close()

>>> for l in lines:
...   # split line into fields
...   fields = line.split()
...   # convert text to numbers
...   freq = float(fields[0])
...   vv = float(fields[1])
...   hh = float(fields[2])
...   # group & append to results
...   all = [freq,vv,hh]
...   results.append(all)
... < hit return >
```

PRINTING THE RESULTS

```
>>> for i in results: print i
[100.0, -20.30…, -31.20…]
[200.0, -22.70…, -33.60…]
```

EXAMPLE FILE: RCS.TXT

```
#freq (MHz)   vv (dB)   hh (dB)
  100          -20.3      -31.2
  200          -22.7      -33.6
```

More compact version

ITERATING ON A FILE AND LIST COMPREHENSIONS

```
>>> results = []
>>> f = open('c:\\rcs.txt','r')
>>> f.readline()
'#freq (MHz)  vv (dB)  hh (dB)\n'
>>> for l in f:
...     all = [float(val) for val in l.split()]
...     results.append(all)
... < hit return >
>>> for i in results:
...     print i
... < hit return >
```

EXAMPLE FILE: RCS.TXT

```
#freq (MHz)   vv (dB)   hh (dB)
  100         -20.3     -31.2
  200         -22.7     -33.6
```

Same thing, one line

OBFUSCATED PYTHON CONTEST...

```
>>> print [[float(val) for val in l.split()] for
...         l in open("c:\\temp\\rcs.txt","r")
...         if l[0] !="#"]
```

EXAMPLE FILE: RCS.TXT

```
#freq (MHz)   vv (dB)   hh (dB)
  100         -20.3     -31.2
  200         -22.7     -33.6
```

Sorting

THE CMP METHOD

```
# The builtin cmp(x,y)
# function compares two
# elements and returns
# -1, 0, 1
# x <  y --> -1
# x == y -->  0
# x >  y -->  1
>>> cmp(0,1)
-1

# By default, sorting uses
# the builtin cmp() method
>>> x = [1,4,2,3,0]
>>> x.sort()
>>> x
[0, 1, 2, 3, 4]
```

CUSTOM CMP METHODS

```
# define a custom sorting
# function to reverse the
# sort ordering
>>> def descending(x,y):
...     return -cmp(x,y)

# Try it out
>>> x.sort(descending)
>>> x
[4, 3, 2, 1, 0]
```

Sorting

SORTING CLASS INSTANCES

```
# Comparison functions for a variety of particle values
>>> def by_mass(x,y):
...     return cmp(x.mass,y.mass)
>>> def by_velocity(x,y):
...     return cmp(x.velocity,y.velocity)
>>> def by_momentum(x,y):
...     return cmp(x.momentum(),y.momentum())

# Sorting particles in a list by their various properties
>>> x = [particle(1.2,3.4),particle(2.1,2.3),particle(4.6,.7)]
>>> x.sort(by_mass)
>>> x

>>> x.sort(by_velocity)
>>> x
[(m:4.6, v:0.7), (m:2.1, v:2.3), (m:1.2, v:3.4)]
>>> x.sort(by_momentum)
>>> x
[(m:4.6, v:0.7), (m:1.2, v:3.4), (m:2.1, v:2.3)]
```

Criticism of Python

FUNCTION ARGUMENTS

```
# All function arguments are called by reference. Changing data in
# subroutine effects global data!
>>> def sum(lst):
...     tot=0
...     for i in range(0,len(lst)):
...         lst[i]+=1
...         tot += lst[i]
...     return tot
>>> a=range(1,4)
>>> sum(a)
9
>>> a
[2,3,4]
# Can be fixed by
>>> a=range(1,4)
>>> a_copy = a[:] # be careful: a_copy = a would not work
>>> sum(a_copy)
9
>>> a
[1,2,3]
```

Criticism of Python

FUNCTION ARGUMENTS

Python does not support something like "const" in C++. If users checks function declaration, it has no clue which arguments are meant as input (unchanged on exit) and which are output

COPYING DATA

User has "no direct contact" with data structures. User might not be aware of data handling. Python is optimized for speed -> references.

```
>>> a=[1,2,3,[4,5]]
>>> b=a[:]
>>> a[0]=2
>>> b
[1,2,3,[4,5]]
>>> a[3][0]=0
>>> b
[1,2,3,[0,5]]
```

```
# Can be fixed by
>>> import copy
>>> a=[1,2,3,[4,5]]
>>> b = copy.deepcopy(a)
>>> a[3][0]=0
>>> b
[1,2,3,[4,5]]
```

Criticism of Python

CLASS DATA

In C++ class declaration uncovers all important information about the class - class members (data and methods). In Python, data comes into existence when used. User needs to read implementation of the class (much more code) to find class data and understand the logic of the class. This is particularly important in large scale codes.

RELODING MODULES

If you import a module in command-line interpreter, but the module was later changed on disc, you can reload the module by typing
reload modulexxx
This reloads the particular modulexxx, but does not recursively reload modules that might also be changed on disc and are imported by the modulexxx.

NumPy

NumPy and SciPy

In 2005 Numarray and Numeric were merged into common project called "NumPy". On top of it, SciPy was build recently and spread very fast in scientific community.

Home: http://www.scipy.org/SciPy

IMPORT NUMPY AND SCIPY

```
>>> from numpy import *
>>> import numpy
>>> numpy.__version__
'1.0.1'
        or better
>>> from scipy import *
>>> import scipy
>>> scipty.__version__
'0.5.2'
```

Introducing Numeric Arrays

SIMPLE ARRAY CREATION

```
>>> a = array([0,1,2,3])
>>> a
array([0, 1, 2, 3])
```

CHECKING THE TYPE

```
>>> type(a)
<type 'array'>
```

NUMERIC TYPE OF ELEMENTS

```
>>> a.typecode()
'l'   # 'l' = Int
```

BYTES IN AN ARRAY ELEMENT

```
>>>
a.itemsize()
4
```

ARRAY SHAPE

```
>>> a.shape
(4,)
>>> shape(a)
(4,)
```

CONVERT TO PYTHON LIST

```
>>> a.tolist()
[0, 1, 2, 3]
```

ARRAY INDEXING

```
>>> a[0]
0
>>> a[0] = 10
>>> a
[10, 1, 2, 3]
```

Array Operations

SIMPLE ARRAY MATH

```
>>> a = array([1,2,3,4])
>>> b = array([2,3,4,5])
>>> a + b
array([3, 5, 7, 9])
```

NumPy defines the following constants:

```
pi = 3.14159265359
e  = 2.71828182846
```

MATH FUNCTIONS

```
# Create array from 0 to 10
>>> x = arange(11.)

# multiply entire array by
# scalar value
>>> a = (2*pi)/10.
>>> a
0.628318530718
>>> a*x
array([ 0.,0.628,…,6.283])

# apply functions to array.
>>> y = sin(a*x)
```

Multi-Dimensional Arrays

MULTI-DIMENSIONAL ARRAYS

```
>>> a = array([[ 0, 1, 2, 3],
               [10,11,12,13]])
>>> a
array([[ 0, 1, 2, 3],
       [10,11,12,13]])
```

(ROWS,COLUMNS)

```
>>> shape(a)
(2, 4)
```

GET/SET ELEMENTS

```
>>> a[1,3]
13
```

column
row

```
>>> a[1,3] = -1
>>> a
array([[ 0, 1, 2, 3],
       [10,11,12,-1]])
```

ADDRESS FIRST ROW USING SINGLE INDEX

```
>>> a[1]
array([10, 11, 12, 13])
```

FLATTEN TO 1D ARRAY

```
>>> a.flat
array(0,1,2,3,10,11,12,-1)
>>> ravel(a)
array(0,1,2,3,10,11,12,-1)
```

A.FLAT AND RAVEL() REFERENCE ORIGINAL MEMORY

```
>>> a.flat[5] = -2
>>> a
array([[ 0, 1, 2, 3],
       [10,-2,12,-1]])
```

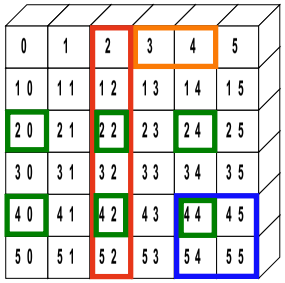
Array Slicing

SLICING WORKS MUCH LIKE STANDARD PYTHON SLICING

```
>>> a[0,3:5]
array([3, 4])

>>> a[4:,4:]
array([[44, 45],
       [54, 55]])

>>> a[:,2]
array([2,12,22,32,42,52])
```



STRIDES ARE ALSO POSSIBLE

```
>>> a[2::2,::2]
array([[20, 22, 24],
       [40, 42, 44]])
```

Slices Are References

Slices are references to memory in original array. Changing values in a slice also changes the original array.

```
>>> a = array([0,1,2])

# create a slice containing only the
# last element of a
>>> b = a[2:3]
>>> b[0] = 10

# changing b changed a!
>>> a
array([ 1,  2, 10])
```

Array Constructor

```
array(sequence, typecode=None, copy=1, savespace=0)
```

sequence - any type of Python sequence. Nested list create multi-dimensional arrays.

typecode - character (string). Specifies the numerical type of the array. If it is None, the constructor makes its best guess at the numeric type.

copy - if **copy=0** and sequence is an array object, the returned array is a reference that data. Otherwise, a copy of the data in **sequence** is made.

savespace - Forces Numeric to use the smallest possible numeric type for the array. Also, it prevents upcasting to a different type during math operations with scalars. (see coercion section for more details)

Array Constructor Examples

FLOATING POINT ARRAYS DEFAULT TO DOUBLE PRECISION

```
>>> a = array([0,1.,2,3])
>>> a.dtype()
'd'
```

notice decimal

BYTES FOR MAIN ARRAY STORAGE

```
# flat assures that
# multidimensional arrays
# work
>>>len(a.flat)*a.itemsize
32
```

USE TYPECODE TO REDUCE PRECISION

```
>>> a = array([0,1.,2,3],'f')
>>> a.dtype()
'f'
>>> len(a.flat)*a.itemsize()
16
```

ARRAYS REFERENCING SAME DATA

```
>>> a = array([1,2,3,4])
>>> b = array(a,copy=0)
>>> b[1] = 10
>>> a
array([ 1, 10,  3,  4])
```

32-bit Typecodes

Character	Bits (Bytes)	Identifier
D	128 (16)	**Complex**, Complex64
F	64 (8)	Complex0, Complex8, Complex16, Complex32
d	64 (8)	**Float**, Float64
f	32 (4)	Float0, Float8, Float16, Float32
l	32 (4)	**Int**
i	32 (4)	Int32
s	16 (2)	Int16
1 (one)	8 (1)	Int8
u	32 (4)	UnsignedInt32
w	16 (2)	UnsignedInt16
b	8 (1)	UnsignedInt8
O	4 (1)	PyObject

Highlighted typecodes correspond to Python's standard Numeric types.

Array Creation Functions

arange(start,stop=None,step=1,typecode=None)

Nearly identical to Python's `range()`. Creates an array of values in the range [start,stop) with the specified `step` value. Allows non-integer values for `start`, `stop`, and `step`. When not specified, `typecode` is derived from the `start`, `stop`, and `step` values.

```
>>> arange(0,2*pi,pi/4)
array([ 0.000, 0.785, 1.571, 2.356, 3.142,
        3.927, 4.712, 5.497])
```

ones(shape,typecode=None,savespace=0)
zeros(shape,typecode=None,savespace=0)

`shape` is a number or sequence specifying the dimensions of the array. If `typecode` is not specified, it defaults to `Int`.

```
>>> ones((2,3),typecode=Float32)
array([[ 1.,  1.,  1.],
       [ 1.,  1.,  1.]],'f')
```

Array Creation Functions (cont.)

identity(n,typecode='l')

Generates an n by n identity matrix with `typecode = Int`.

```
>>> identity(4)
array([[1, 0, 0, 0],
       [0, 1, 0, 0],
       [0, 0, 1, 0],
       [0, 0, 0, 1]])
>>> identity(4,'f')
array([[ 1.,  0.,  0.,  0.],
       [ 0.,  1.,  0.,  0.],
       [ 0.,  0.,  1.,  0.],
       [ 0.,  0.,  0.,  1.]],'f')
```

Mathematic Binary Operators

```
a + b → add(a,b)
a - b → subtract(a,b)
a % b → remainder(a,b)
a * b → multiply(a,b)
a / b → divide(a,b)
a ** b → power(a,b)
```

MULTIPLY BY A SCALAR

```
>>> a = array((1,2))
>>> a*3.
array([3., 6.])
```

ELEMENT BY ELEMENT ADDITION

```
>>> a = array([1,2])
>>> b = array([3,4])
>>> a + b
array([4, 6])
```

ADDITION USING AN OPERATOR FUNCTION

```
>>> add(a,b)
array([4, 6])
```

IN PLACE OPERATION

```
# Overwrite contents of a.
# Saves array creation
# overhead
>>> add(a,b,a) # a += b
array([4, 6])
>>> a
array([4, 6])
```

Comparison and Logical Operators

equal	(==)	not_equal	(!=)	greater	(>)
greater_equal	(>=)	less	(<)	less_equal	(<=)
logical_and	(and)	logical_or	(or)	logical_xor	
logical_not	(not)				

2D EXAMPLE

```
>>> a = array(((1,2,3,4),(2,3,4,5)))
>>> b = array(((1,2,5,4),(1,3,4,5)))
>>> a == b
array([[1, 1, 0, 1],
       [0, 1, 1, 1]])
# functional equivalent
>>> equal(a,b)
array([[1, 1, 0, 1],
       [0, 1, 1, 1]])
```

Trig and Other Functions

TRIGONOMETRIC

sin(x)	sinh(x)
cos(x)	cosh(x)
arccos(x)	arccosh(x)
arctan(x)	arctanh(x)
arcsin(x)	arcsinh(x)
arctan2(x,y)	

OTHERS

exp(x)	log(x)
log10(x)	sqrt(x)
absolute(x)	conjugate(x)
negative(x)	ceil(x)
floor(x)	fabs(x)
hypot(x,y)	fmod(x,y)
maximum(x,y)	minimum(x,y)

hypot(x,y)

Element by element distance calculation using $\sqrt{x^2 + y^2}$

Bitwise Operators

bitwise_and	(&)	invert	(~)	right_shift(a,shifts)	
bitwise_or	(|)	bitwise_xor		left_shift (a,shifts)	

BITWISE EXAMPLES

```
>>> a = array((1,2,4,8))
>>> b = array((16,32,64,128))
>>> bitwise_and(a,b)
array([ 17,  34,  68, 136])

# bit inversion
>>> a = array((1,2,3,4),UnsignedInt8)
>>> invert(a)
array([254, 253, 252, 251],'b')

# surprising type conversion
>>> left_shift(a,3)
array([ 8, 16, 24, 32],'i')
```

Changed from UnsignedInt8 to Int32

SciPy

Basic Environment

CONVENIENT MATRIX GENERATION AND MANIPULATION

```
>>> A = mat('1,2,4;4,5,6;7,8,9')
>>> A=mat([[1,2,4],[4,5,6],[7,8,9]])
>>> print A
Matrix([[1, 2, 4],
        [2, 5, 3],
        [7, 8, 9]])
>>> print A**4
Matrix([[ 6497,  9580,  9836],
        [ 7138, 10561, 10818],
        [18434, 27220, 27945]])
>>> print A*A.I
Matrix([[ 1.,  0.,  0.],
        [ 0.,  1.,  0.],
        [ 0.,  0.,  1.]])
>>> print A.T
Matrix([[1, 2, 7],
        [2, 5, 8],
        [4, 3, 9]])
```

Simple creation of matrix with ";" meaning row separation

Matrix Power

Matrix Multiplication and Matrix Inverse

Matrix Transpose

Basic Environment

CONVENIENCE FUNCTIONS

```
>>> info(linspace)
 linspace(start, stop, num=50, endpoint=1, retstep=0)

Evenly spaced samples.

Return num evenly spaced samples from start to stop.  If
endpoint=1 then
last sample is stop. If retstep is 1 then return the step value
used.
>>> linspace(-1,1,5)
array([-1. , -0.5,  0. ,  0.5,  1. ])
>>> r_[-1:1:5j]
array([-1. , -0.5,  0. ,  0.5,  1. ])
>>> logspace(0,3,4)
array([    1.,    10.,   100.,  1000.])
>>> info(logspace)
 logspace(start, stop, num=50, endpoint=1)

Evenly spaced samples on a logarithmic scale.

Return num evenly spaced samples from 10**start to 10**stop.  If
endpoint=1 then last sample is 10**stop.
```

`info` help system for scipy

similar to `dir` for the rest of python

`linspace` get equally spaced points.

`r_[]` also does this (shorthand)

`logspace` get equally spaced points in log10 domain

More Basic Functions

TYPE HANDLING

iscomplexobj	real_if_close	isnan
iscomplex	isscalar	nan_to_num
isrealobj	isneginf	common_type
isreal	isposinf	cast
imag	isinf	typename
real	isfinite	

SHAPE MANIPULATION

squeeze	vstack	split
atleast_1d	hstack	hsplit
atleast_2d	column_stack	vsplit
atleast_3d	dstack	dsplit
apply_over_axes	expand_dims	apply_along_axis

OTHER USEFUL FUNCTIONS

select	unwrap	roots
extract	sort_complex	poly
insert	trim_zeros	any
fix	fliplr	all
mod	flipud	disp
amax	rot90	unique
amin	eye	extract
ptp	diag	insert
sum	factorial	nansum
cumsum	factorial2	nanmax
prod	comb	nanargmax
cumprod	pade	nanargmin
diff	derivative	nanmin
angle	limits.XXXX	

Input and Output

scipy.io --- Reading and writing ASCII files

textfile.txt

```
Student Test1   Test2   Test3   Test4

Jane    98.3    94.2    95.3    91.3
Jon     47.2    49.1    54.2    34.7
Jim     84.2    85.3    94.1    76.4
```

Read from column 1 to the end

Read from line 3 to the end

```
>>> a = io.read_array('textfile.txt',columns=(1,-1),lines=(3,-1))
>>> print a
[[ 98.3  94.2  95.3  91.3]
 [ 47.2  49.1  54.2  34.7]
 [ 84.2  85.3  94.1  76.4]]
>>> b = io.read_array('textfile.txt',columns=(1,-2),lines=(3,-2))
>>> print b
[[ 98.3  95.3]
 [ 84.2  94.1]]
```

Read from column 1 to the end every second column

Read from line 3 to the end every second line

Input and Output

scipy.io --- Reading and writing raw binary files

fid = fopen(file_name, permission='rb', format='n')

Class for reading and writing binary files into Numeric arrays.

- file_name — The complete path name to the file to open.
- permission — Open the file with given permissions: ('r', 'w', 'a') for reading, writing, or appending. This is the same as the mode argument in the builtin open command.
- format — The byte-ordering of the file: (['native', 'n'], ['ieee-le', 'l'], ['ieee-be', 'b']) for native, little-endian, or big-endian.

Methods

read	read data from file and return Numeric array
write	write to file from Numeric array
fort_read	read Fortran-formatted binary data from the file.
fort_write	write Fortran-formatted binary data to the file.
rewind	rewind to beginning of file
size	get size of file
seek	seek to some position in the file
tell	return current position in file
close	close the file

Few examples

Examples of SciPy use

Integration

Suppose we want to integrate Bessel function

$$\int_0^x dt J_1(t)/t$$

```
>>> info(integrate)
.....<documentation of integrate module>.....
>>> integrate.quad(lambda t:
special.j1(t)/t,0,pi)
(1.062910971494,1.18e-14)
```

j1int.py module:

```
from scipy import *
def fun(x):
    return integrate.quad(lambda t: special.j1(t)/t,0,x)

x=r_[0:30:0.01]
for tx in x:
    print tx, fun(tx)[0]
```

Minimization

Suppose we want to minimize the function

$$(x-a)^2+(y-b)^2=\min$$

```
>>> from scipy import *
>>> import scipy
>>> info(scipy)
.... <documentation of all available modules>
>>> info(optimize)
>>> info(optimize.fmin_powell)

>>> def func((x,y),(a,b)): return (x-a)**2+(y-b)**2

>>> optimize.fmin_powell(func, (0,0), ((5,6),))
Opimization terminated successfully,
     Current function value: 0.00000
     Iterations: 2
     Function evaluations: 38
array([5.,6.])
```

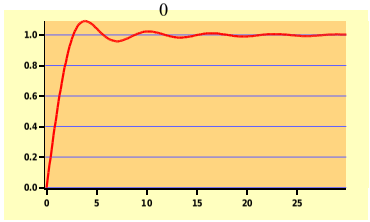
Starting guess

additional arguments

Root finding and integration

The function $\int_0^x dtJ_1(t)/t == 1$

$$\int_0^x dtJ_1(t)/t$$



has many solutions. Suppose we want to find all solution in the range [0:100]

Put it all together

```
from scipy import *
"""
  Finds all solutions of the equation Integrate[j1(t)/t,{t,0,x}] == 1
  in the range x=[0,100]
"""

def func(x,a):
    " Computes Integrate[j1(t)/t,{t,0,x}] - a"
    return integrate.quad(lambda t: special.j1(t)/t, 0, x)[0] - a

# Finds approxiate solutions of the equation in the range [0:100]
x = r_[0:100:0.2]                 # creates an equaly spaced array
b = map(lambda t: func(t,1), x)   # evaluates function on this array

z = [];                           # approximate solutions of the equation
for i in range(1,len(b)):               # if the function changes sign,
    if (b[i-1]*b[i]<0): z.append(x[i]) # the solution is bracketed

print "Zeros of the equation in the interval [0:100] are"
j=0
for zt in z:
    print j, optimize.fsolve(func,zt,(1,))  # calling root finding
routine, finds all zeros.
    j+=1
```

It takes around 2 seconds to get

```
Zeros of the equation in the interval [0:100] are
0 2.65748482457
1 5.67254740317
2 8.75990144967

Linear Algebra

scipy.linalg --- FAST LINEAR ALGEBRA

- **Uses ATLAS if available --- very fast**
- **Low-level access to BLAS and LAPACK routines in modules `linalg.fblas`, and `linalg.flapack` (FORTRAN order)**
- **High level matrix routines**
  - **Linear Algebra Basics: `inv`, `solve`, `det`, `norm`, `lstsq`, `pinv`**
  - **Decompositions: `eig`, `lu`, `svd`, `orth`, `cholesky`, `qr`, `schur`**
  - **Matrix Functions: `expm`, `logm`, `sqrtm`, `cosm`, `coshm`, `funm` (general matrix functions)**

Some simple examples

```
>>> A=matrix(random.rand(5,5))  # creates random matrix
>>> A.I
<inverse of the random matrix>
>>> linalg.det(A)
<determinant of the matrix>
>>> linalg.eigvals(A)
<eigenvalues only>
>>> linalg.eig(A)
<eigenvalues and eigenvectors>
>>> linalg.svd(A)
<SVD decomposition>
>>> linalg.cholesky(A)
<Cholesky decomposition for positive definite A>
>>> B=matrix(random.rand(5,5))
>>> linalg.solve(A,B)
<Solution of the equation A.X=B>
```

Special Functions

scipy.special

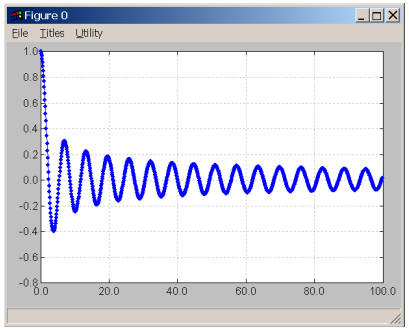
Includes over 200 functions:

Airy, Elliptic, Bessel, Gamma, HyperGeometric, Struve, Error, Orthogonal Polynomials, Parabolic Cylinder, Mathieu, Spheroidal Wave, Kelvin

FIRST ORDER BESSEL EXAMPLE

```
#environment setup
>>> import gui_thread
>>> gui_thread.start()
>>> from scipy import *
>>> import scipy.plt as plt

>>> x = r_[0:100:0.1]
>>> j0x = special.j0(x)
>>> plt.plot(x,j0x)
```

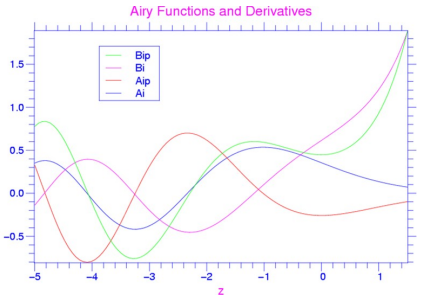


Special Functions

scipy.special

AIRY FUNCTIONS EXAMPLE

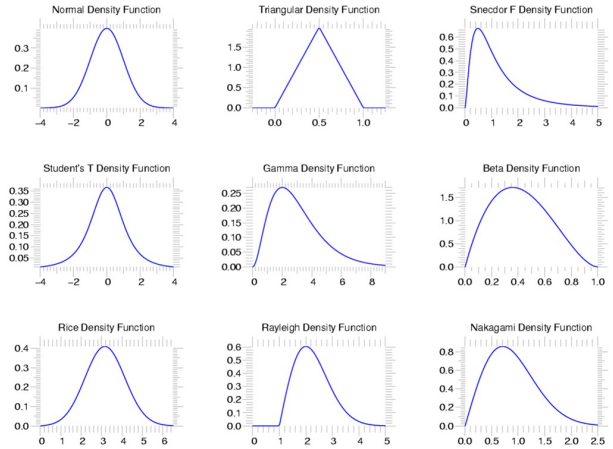
```
>>> z = r_[-5:1.5:100j]
>>> vals = special.airy(z)
>>> xplt.figure(0, frame=1,
                color='blue')
>>> xplt.matplot(z,vals)
>>> xplt.legend(['Ai', 'Aip',
        'Bi','Bip'],
   color='blue')
>>> xplt.xlabel('z',
   color='magenta')
>>> xplt.title('Airy
   Functions and
   Derivatives')
```



Statistics

scipy.stats --- Continuous Distributions

over 80 continuous distributions!



Methods

- `pdf`
- `cdf`
- `rvs`
- `ppf`
- `stats`

Statistics

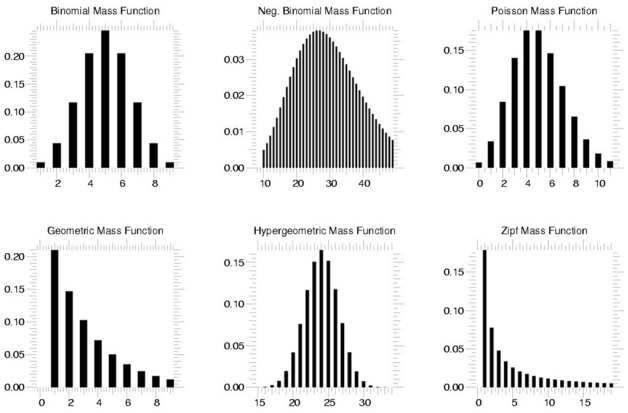
scipy.stats --- Basic Statistical Calculations for samples

• `stats.mean (also mean)`	**compute the sample mean**
• `stats.std (also std)`	**compute the sample standard deviation**
• `stats.var`	**sample variance**
• `stats.moment`	**sample central moment**
• `stats.skew`	**sample skew**
• `stats.kurtosis`	**sample kurtosis**

Statistics

scipy.stats --- Discrete Distributions

10 standard discrete distributions (plus any arbitrary finite RV)



Methods

- `pdf`
- `cdf`
- `rvs`
- `ppf`
- `stats`

Interpolation

scipy.interpolate --- General purpose Interpolation

- **1-d linear Interpolating Class**
  - Constructs callable function from data points
  - Function takes vector of inputs and returns linear interpolants
- **1-d and 2-d spline interpolation (FITPACK)**
  - Splines up to order 5
  - Parametric splines

Integration

scipy.integrate --- General purpose Integration

- **Ordinary Differential Equations (ODE)**

  `integrate.odeint, integrate.ode`

- **Samples of a 1-d function**

  `integrate.trapz` (trapezoidal Method), `integrate.simps` (Simpson Method), `integrate.romb` (Romberg Method)

- **Arbitrary callable function**

  `integrate.quad` (general purpose), `integrate.dblquad` (double integration), `integrate.tplquad` (triple integration), `integrate.fixed_quad` (fixed order Gaussian integration), `integrate.quadrature` (Gaussian quadrature to tolerance), `integrate.romberg` (Romberg)

Optimization

scipy.optimize --- unconstrained minimization and root finding

- **Unconstrained Optimization**

  `fmin` (Nelder-Mead simplex), `fmin_powell` (Powell's method), `fmin_bfgs` (BFGS quasi-Newton method), `fmin_ncg` (Newton conjugate gradient), `leastsq` (Levenberg-Marquardt), `anneal` (simulated annealing global minimizer), `brute` (brute force global minimizer), **brent** (excellent 1-D minimizer), **golden**, **bracket**

- **Constrained Optimization**

  `fmin_l_bfgs_b`, `fmin_tnc` (truncated newton code), `fmin_cobyla` (constrained optimization by linear approximation), `fminbound` (interval constrained 1-d minimizer)

- **Root finding**

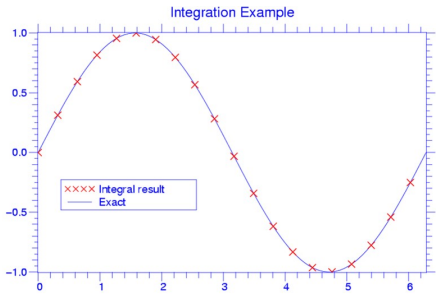
  `fsolve` (using MINPACK), `brentq`, `brenth`, `ridder`, `newton`, `bisect`, `fixed_point` (fixed point equation solver)

Integration

scipy.integrate --- Example

```
>>> def func(x):
    return integrate.quad(cos,0,x)[0]
>>> vecfunc = vectorize(func)

>>> x = r_[0:2*pi:100j]
>>> x2 = x[::5]
>>> y = sin(x)
>>> y2 = vecfunc(x2)
>>> xplt.plot(x,y,x2,y2,'rx')
```

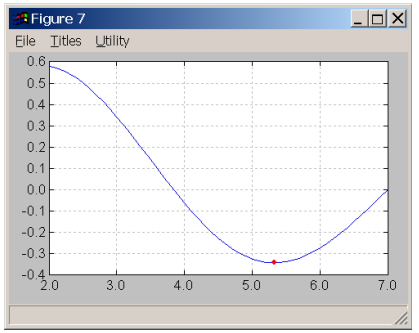


Optimization

EXAMPLE: MINIMIZE BESSEL FUNCTION

```
# minimize 1st order bessel
# function between 4 and 7
>>> from scipy.special import j1
>>> from scipy.optimize import \
    fminbound

>>> x = r_[2:7.1:.1]
>>> j1x = j1(x)
>>> plt.plot(x,j1x,'-')
>>> plt.hold('on')
>>> j1_min = fminbound(j1,4,7)
>>> plt.plot(x,j1_min,'ro')
```



Optimization

EXAMPLE: SOLVING NONLINEAR EQUATIONS

Solve the non-linear equations

$$3x_0 - \cos(x_1 x_2) + a = 0$$
$$x_0^2 - 81(x_1 + 0.1)^2 + \sin(x_2) + b = 0$$
$$e^{-x_0 x_1} + 20x_2 + c = 0$$

starting location for search

```
>>> def nonlin(x,a,b,c):
>>>     x0,x1,x2 = x
>>>     return [3*x0-cos(x1*x2)+ a,
>>>             x0*x0-81*(x1+0.1)**2
                  + sin(x2)+b,
>>>             exp(-x0*x1)+20*x2+c]
>>> a,b,c = -0.5,1.06,(10*pi-3.0)/3
>>> root = optimize.fsolve(nonlin,
                [0.1,0.1,-0.1],args=(a,b,c))
>>> print root
>>> print nonlin(root,a,b,c)
[ 0.5     0.     -0.5236]
[0.0, -2.231104190e-12, 7.46069872e-14]
```

Optimization

EXAMPLE: MINIMIZING ROSENBROCK FUNCTION

Rosenbrock function $f(\mathbf{x}) = \sum_{i=1}^{N-1} 100\left(x_i - x_{i-1}^2\right)^2 + (1 - x_{i-1})^2.$

WITHOUT DERIVATIVE

```
>>> rosen = optimize.rosen
>>> import time
>>> x0 = [1.3,0.7,0.8,1.9,1.2]
>>> start = time.time()
>>> xopt = optimize.fmin(rosen,
x0, avegtol=1e-7)
>>> stop = time.time()
>>> print_stats(start, stop, xopt)
Optimization terminated successfully.
     Current function value: 0.000000
     Iterations: 316
     Function evaluations: 533
Found in 0.0805299282074 seconds
Solution: [ 1.  1.  1.  1.  1.]
Function value: 2.67775760157e-15
Avg. Error: 1.5323906899e-08
```

USING DERIVATIVE

```
>>> rosen_der = optimize.rosen_der
>>> x0 = [1.3,0.7,0.8,1.9,1.2]
>>> start = time.time()
>>> xopt = optimize.fmin_bfgs(rosen,
x0, fprime=rosen_der, avegtol=1e-7)
>>> stop = time.time()
>>> print_stats(start, stop, xopt)
Optimization terminated successfully.
     Current function value: 0.000000
     Iterations: 111
     Function evaluations: 266
     Gradient evaluations: 112

Function value: 1.3739103475e-18
Avg. Error: 1.13246034772e-10
```

GA and Clustering

scipy.ga --- Basic Genetic Algorithm Optimization

Routines and classes to simplify setting up a genome and running a genetic algorithm evolution

scipy.cluster --- Basic Clustering Algorithms

- **Observation whitening** `cluster.vq.whiten`
- **Vector quantization** `cluster.vq.vq`
- **K-means algorithm** `cluster.vq.kmeans`
